New Technology in IT Application Development

Deploy an ML model from a research environment setting to “production”. Here are the high-level steps to deploy an ML model:

1. Export your pre-trained model to the ONNX format.
2. Create a small Rest API application to query your model. Web frameworks to do should using Flask, which is small and lightweight. Server is highly recommended to use a production-ready WSGI HTTP server like Gunicorn with Nginx as a proxy. For more info, check out this guide.
3. Containerize your ML application using Docker.
4. Deploy and scale your ML application with Kubernetes. (OPTIONAL)
5. Monitor your ML application. You can use a Prometheus exporter for Flask applications like this one.
